Case Study: Social Media Feed Sorting System (Merge Sort)

A social media platform must sort millions of posts based on timestamps and relevance to

ensure timely content delivery. Analyze how Merge Sort can be applied to handle large-scale data efficiently while maintaining stability. Identify challenges such as real-time updates and scalability. Apply divide and conquer principles to explain the sorting mechanism. Analyze time complexity and design a suitable solution, justifying why Merge Sort is appropriate.

Report

Case Study

Social Media Feed Sorting System using Merge Sort

Aim

To implement Merge Sort for sorting millions of social media posts based on timestamps while maintaining stability and analyzing its efficiency for large-scale social media feed management.

Objective

- **Implement Merge Sort for sorting posts.**
- **Apply Divide and Conquer strategy.**
- **Maintain stable ordering of posts.**
- **Analyze time complexity.**
- **Study scalability and real-time challenges.**

Introduction

Social media platforms like Instagram, Facebook, Twitter (X), and LinkedIn receive millions of posts every minute. These posts must be sorted efficiently so users always see the newest and most relevant content.

Merge Sort is a stable Divide and Conquer algorithm capable of handling very large datasets efficiently.

Problem Statement

A social media platform stores millions of posts.

The system must:

- Sort by latest timestamp.
- Preserve the order of posts with equal timestamps.
- Handle large-scale datasets.
- Deliver feeds quickly.

Algorithm

1. Divide posts into two halves.
2. Continue dividing until each subarray has one post.
3. Merge sorted halves.
4. Compare timestamps.
5. Place latest timestamp first.
6. Repeat until entire array becomes sorted.

Divide and Conquer Principle

Divide

Split the post list into two halves.

Posts

↓

Left Half

Right Half

Conquer

Recursively sort both halves.

Left

Working Example

Before Sorting

Post ID Timestamp

101 1691002300

102 1691005200

103 1690999900

104 1691004300

Post ID Timestamp

105	1691006200
-----	------------

↓

After Merge Sort

Post ID Timestamp

105	1691006200
-----	------------

102	1691005200
-----	------------

104	1691004300
-----	------------

101	1691002300
-----	------------

103	1690999900
-----	------------

Time Complexity

Case Complexity

Best	$O(n \log n)$
------	---------------

Average	$O(n \log n)$
---------	---------------

Worst	$O(n \log n)$
-------	---------------

Space Complexity

$O(n)$

Extra memory is required during merging.

Advantages

- Stable sorting algorithm.
- Predictable performance.
- Efficient for huge datasets.
- Suitable for external sorting.
- Parallelizable.

Challenges

Real-Time Updates

- New posts arrive every second.
- Frequent re-sorting is required.

Scalability

- Millions of posts increase memory usage.
- Distributed servers may be required.

Memory Consumption

Merge Sort requires extra auxiliary memory.

High Throughput

The system must process thousands of posts per second.

Why Merge Sort is Appropriate

- Stable sorting preserves equal-timestamp order.
- Guaranteed $O(n \log n)$ performance.
- Efficient for external storage and distributed systems.
- Supports parallel processing.
- Widely used for large-scale data processing.

Applications

- Facebook News Feed
- Instagram Feed
- Twitter/X Timeline
- LinkedIn Feed
- News Aggregation Systems

Analysis

Merge Sort divides large datasets into smaller parts, sorts them independently, and merges them efficiently. Because it guarantees $O(n \log n)$ performance regardless of input order, it performs consistently even with millions of posts. Its stability ensures that posts with identical timestamps maintain their original order, which is valuable for fairness and consistent user experience. Although it requires additional memory during merging, its predictable performance and scalability make it a strong choice for large-scale feed sorting.

Result

The Merge Sort implementation successfully sorted social media posts by timestamp while preserving stable ordering. The algorithm demonstrated consistent $O(n \log n)$ time complexity, making it suitable for efficiently managing large-scale social media feeds.

Run

Output

Clear

```
1 #include <stdio.h>
2 #include <string.h>
3
4 #define MAX 100
5
6 // Structure to represent a social media post
7 struct Post
8 {
9     int id;
10    long timestamp;
11    int relevance;
12 };
13
14 // Merge function
15 void merge(struct Post posts[], int left, int mid, int right)
16 {
17     int n1 = mid - left + 1;
18     int n2 = right - mid;
19
20     struct Post L[MAX], R[MAX];
21
22     int i, j, k;
23
```

Before Sorting:

ID	Timestamp	Relevance
101	1691002300	85
102	1691005200	60
103	1690999900	92
104	1691004300	75
105	1691006200	88

After Sorting (Latest Timestamp First):

ID	Timestamp	Relevance
105	1691006200	88
102	1691005200	60
104	1691004300	75
101	1691002300	85
103	1690999900	92

=== Code Execution Successful ===

```
main.c
24 for(i = 0; i < n1; i++)
25     L[i] = posts[left + i];
26
27 for(j = 0; j < n2; j++)
28     R[j] = posts[mid + 1 + j];
29
30 i = 0;
31 j = 0;
32 k = left;
33
34 // Sort by timestamp (latest first)
35 while(i < n1 && j < n2)
36 {
37     if(L[i].timestamp >= R[j].timestamp)
38     {
39         posts[k] = L[i];
40         i++;
41     }
42     else
43     {
44         posts[k] = R[j];
45         j++;
46     }
47 }
```
